

AI-Accelerated Software Development

Helping small teams build like big teams.

A month of meetings and hand-offs becomes a morning - for well-scoped work, when your team knows how to steer, verify, and stay in charge.

This is a developer-only, hands-on course for teams that need to turn business ideas into working software while preserving review, security, data boundaries, and human accountability.

What participants learn

- Turn ideas into intentions, testable requirements, and implementation plans.
- Direct coding agents to build real applications with authentication and per-user data.
- Verify in a browser, inspect code, run quality gates, and repair failures at the root.
- Research an existing codebase before changing it.
- Set agent authority, human decision boundaries, and evidence requirements by risk.
- Maintain canonical skills and specialized agents across Cursor, Claude Code, and Codex.
- Evaluate and route models using evidence from the organization's own work.

Governance, risk, and compliance

Governance

Define what agents may read, change, run, publish, or deploy; where people approve; and who owns each decision.

Risk

Classify data, tools, and changes by consequence, then match them to evidence, rollback, monitoring, and stop conditions.

Compliance

Translate applicable law, contracts, security policy, and audit needs into repository guidance, controls, evidence, and exceptions.

The five-day progression

Day	Focus	Build and evidence
1	Pipeline and real apps	First agent-built app; authenticated SaaS-style slice. Supplied social intentions may be native iOS or equivalent web implementations.
2	Quality and brownfield understanding	Automated review loop; evidence-backed research packet on an existing codebase.
3	Agent protocols and capability lifecycle	Inspectable multi-agent dashboard; searchable, governed skills library.
4	Model evaluation and routing	Model comparison lab scored against organization-relevant prompts.
5	Company-owned AI Program and GRC	Navigable governance application that exposes what is missing, stale, changing, conflicting, or unowned.

The take-home product

Every team leaves with a started, company-owned AI Program: one folder-backed governance/GRC hierarchy, Full/Essential/Light profiles, decision and evidence patterns, maintained capabilities, and an application for people and agents to navigate and question the record.

Who it is for

- Professional software developers and senior developers
- Hands-on technical leads and engineering managers
- Platform, QA automation, and DevOps engineers working in code
- Development teams adopting a structured agentic workflow

Cohort preparation

Participants need Git, terminal, and code-reading fluency plus client-approved access to Cursor, Claude Code, or Codex. Web is the cross-platform teaching default. SwiftUI/Xcode is an optional Mac-only specialization, and the supplied iOS social efforts may be changed to web.
